

Weak Entity Sets

- An entity set that does not have a primary key is referred to as a weak entity set.
- The existence of a weak entity set depends on the existence of a identifying entity set
 - it must relate to the identifying entity set via a total, one-tomany relationship set from the identifying to the weak entity set
 - Identifying relationship depicted using a double diamond
- ☐ The **discriminator** (or partial key) of a weak entity set is the set of attributes that distinguishes among all the entities of a weak entity set.
- ☐ The primary key of a weak entity set is formed by the primary key of the strong entity set on which the weak entity set is existence dependent, plus the weak entity set's discriminator.

Weak Entity Sets (Cont.)

- We underline the discriminator of a weak entity set with a dashed line.
- We put the identifying relationship of a weak entity in a double diamond.
- Discriminator of the weak entity set is underlined by dashed lines
- □ Primary key for section (course_id, sec_id, semester, year)

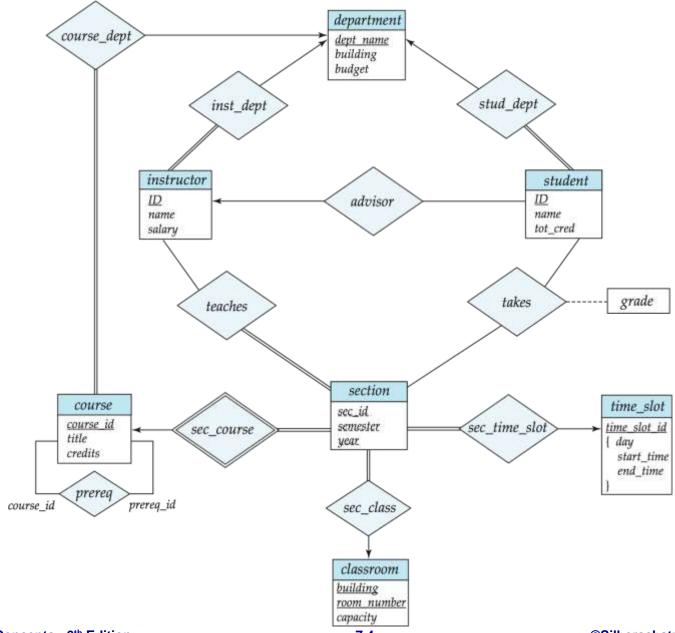

Weak Entity Sets (Cont.)

- Note: the primary key of the strong entity set is not explicitly stored with the weak entity set,
 - it is implicit in the identifying relationship.
- If course_id were explicitly stored, section could be made a strong entity
 - but then there is an implicit relationship defined by the attribute course_id common to course and section
 - and the implicit relationship duplicates the explicit relationship between section and course

E-R Diagram for a University Enterprise

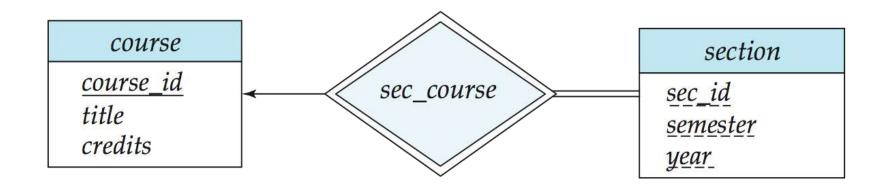

Reduction to Relational Schemas

Attributes

- A strong entity set reduces to a schema with the same attributes student(<u>ID</u>, name, tot_cred)
- A weak entity set becomes a table that includes a column for the primary key of the identifying strong entity set section (<u>course_id</u>, <u>sec_id</u>, <u>sem</u>, <u>year</u>)

Representing Relationship Sets

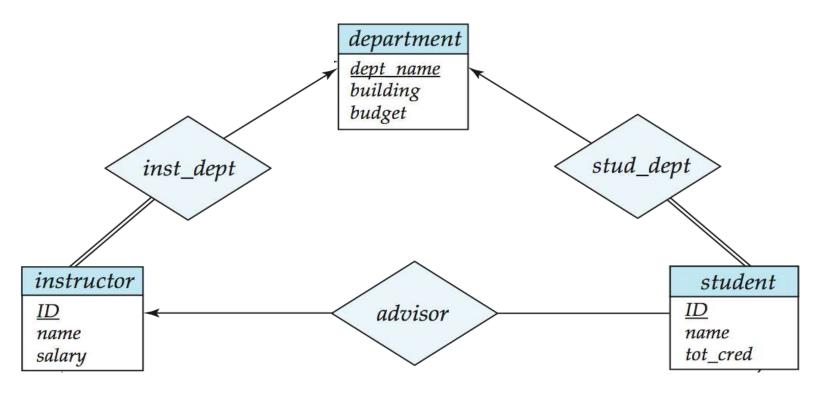

- A many-to-many relationship set is represented as a schema with attributes for the primary keys of the two participating entity sets, and any descriptive attributes of the relationship set.
- Example: schema for relationship set advisor
 advisor = (<u>s id, i id</u>)

Redundancy of Schemas

- Many-to-one and one-to-many relationship sets that are total on the many-side can be represented by adding an extra attribute to the "many" side, containing the primary key of the "one" side
- Example: Instead of creating a schema for relationship set inst_dept, add an attribute dept_name to the schema arising from entity set instructor

Redundancy of Schemas (Cont.)

- For one-to-one relationship sets, either side can be chosen to act as the "many" side
 - That is, extra attribute can be added to either of the tables corresponding to the two entity sets
- If participation is partial on the "many" side, replacing a schema by an extra attribute in the schema corresponding to the "many" side could result in null values
- The schema corresponding to a relationship set linking a weak entity set to its identifying strong entity set is redundant.
 - Example: The section schema already contains the attributes that would appear in the sec_course schema

Composite and Multivalued Attributes

instructor

```
ID
name
  first_name
   middle_initial
   last_name
address
   street
      street_number
      street_name
      apt_number
   city
   state
   zip
{ phone_number }
date_of_birth
age()
```

- Composite attributes are flattened out by creating a separate attribute for each component attribute
 - Example: given entity set instructor with composite attribute name with component attributes first_name and last_name the schema corresponding to the entity set has two attributes name_first_name and name_last_name
 - Prefix omitted if there is no ambiguity
- Ignoring multivalued attributes, extended instructor schema is
 - instructor(ID, first_name, middle_initial, last_name, street_number, street_name, apt_number, city, state, zip_code, date_of_birth)

Composite and Multivalued Attributes

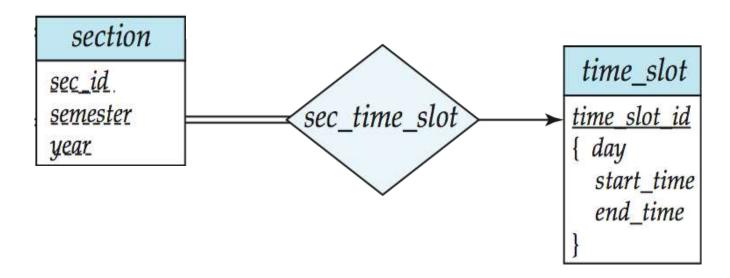

- □ A multivalued attribute *M* of an entity *E* is represented by a separate schema *EM*
 - Schema EM has attributes corresponding to the primary key of E and an attribute corresponding to multivalued attribute M
 - Example: Multivalued attribute phone_number of instructor is represented by a schema: inst_phone= (<u>ID</u>, <u>phone_number</u>)
 - Each value of the multivalued attribute maps to a separate tuple of the relation on schema EM
 - For example, an *instructor* entity with primary key 22222 and phone numbers 456-7890 and 123-4567 maps to two tuples:

(22222, 456-7890) and (22222, 123-4567)

Multivalued Attributes (Cont.)

- Special case:entity time_slot has only one attribute other than the primary-key attribute, and that attribute is multivalued
 - Optimization: Don't create the relation corresponding to the entity, just create the one corresponding to the multivalued attribute
 - □ time_slot(<u>time_slot_id, day, start_time</u>, end_time)
 - Caveat: time_slot attribute of section (from sec_time_slot) cannot be a foreign key due to this optimization

Extended ER Features

- □ Specialization/Generalization
- □ Aggregation (see book for details)

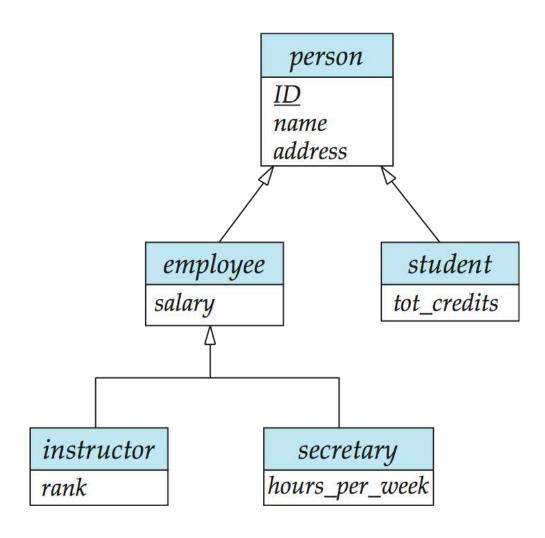

Extended E-R Features: Specialization

- □ Top-down design process; we designate subgroupings within an entity set that are distinctive from other entities in the set.
- These subgroupings become lower-level entity sets that have attributes or participate in relationships that do not apply to the higher-level entity set.
- Depicted by a triangle component labeled ISA (E.g. instructor "is a" person).
- Attribute inheritance a lower-level entity set inherits all the attributes and relationship participation of the higher-level entity set to which it is linked.

Specialization Example

Design Constraints on a Specialization/Generalization

- Constraint on which entities can be members of a given lower-level entity set.
 - condition-defined
 - Example: all customers over 65 years are members of senior-citizen entity set; senior-citizen ISA person.
 - user-defined
- Constraint on whether or not entities may belong to more than one lower-level entity set within a single generalization.

Disjoint

- an entity can belong to only one lower-level entity set
- Noted in E-R diagram by having multiple lower-level entity sets link to the same triangle

Overlapping

an entity can belong to more than one lower-level entity set

Design Constraints on a Specialization/Generalization (Cont.)

- Completeness constraint -- specifies whether or not an entity in the higher-level entity set must belong to at least one of the lower-level entity sets within a generalization.
 - total : an entity must belong to one of the lower-level entity sets
 - partial: an entity need not belong to one of the lower-level entity sets

Representing Specialization via Schemas

Method 1:

- Form a schema for the higher-level entity
- Form a schema for each lower-level entity set, include primary key of higher-level entity set and local attributes

schema	attributes
person	ID, name, street, city
student	ID, tot_cred
employee	ID, salary

Drawback: getting information about, an employee requires accessing two relations, the one corresponding to the lowlevel schema and the one corresponding to the high-level schema

Representing Specialization as Schemas (Cont.)

Method 2:

 Form a schema for each entity set with all local and inherited attributes

schema	attributes
person	ID, name, street, city
student	ID, name, street, city, tot_cred
employee	ID, name, street, city, salary

- If specialization is total, the schema for the generalized entity set (person) not required to store information
 - Can be defined as a "view" relation containing union of specialization relations
 - But explicit schema may still be needed for foreign key constraints
- Drawback: name, street and city may be stored redundantly for people who are both students and employees

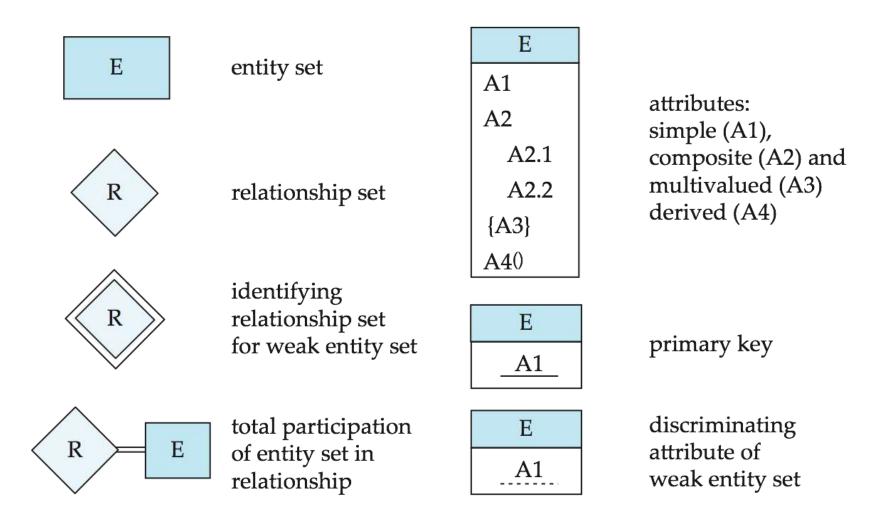

How about doing another ER design interactively on the board?

Database System Concepts, 6th Ed.

Chen IDE1FX (Crows feet notation)

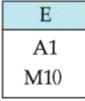

UML

- UML: Unified Modeling Language
- □ UML has many components to graphically model different aspects of an entire software system
- UML Class Diagrams correspond to E-R Diagram, but several differences.

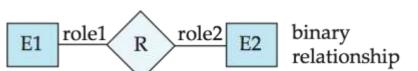

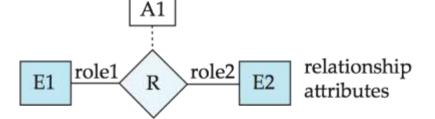

ER vs. UML Class Diagrams

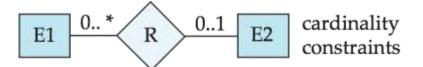

ER Diagram Notation

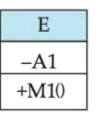

entity with attributes (simple, composite, multivalued, derived)

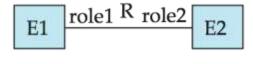

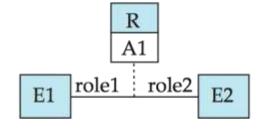

Equivalent in UML

class with simple attributes and methods (attribute prefixes: + = public, -= private, # = protected)

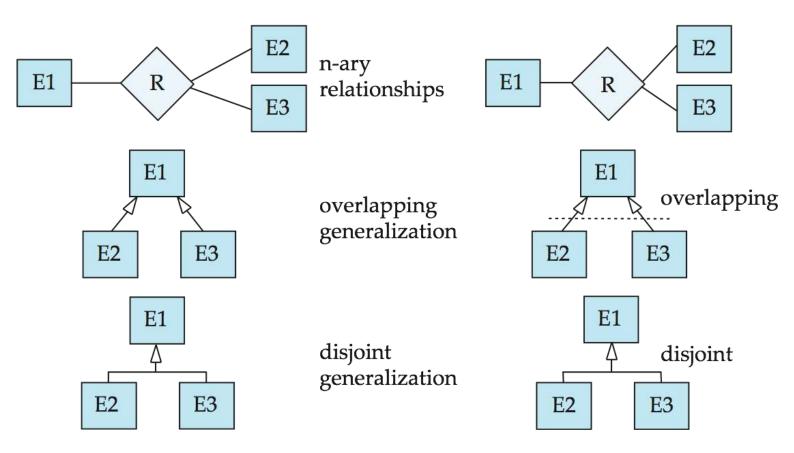

*Note reversal of position in cardinality constraint depiction

ER vs. UML Class Diagrams

ER Diagram Notation

Equivalent in UML

^{*}Generalization can use merged or separate arrows independent of disjoint/overlapping
